PSY30100-03 -- Assignment 9

Chapter 12:
One-Way Analysis of Variance
(One-Way ANOVA)

TA: Laura Lu
November 16, 2009

Problem 1:

- Please describe rationale of one-way ANOVA and the F ratio.

Ans: (You may have your own answers)

One-way ANOVA is the technique used to determine whether more than two population means are equal when there is only one factor or grouping variable in the experiment.

The F-ratio is a ratio which measures the between-group variation compared with the within-group variation. When all group populations have the same standard deviation and the same mean, then this F ratio has the F(DFB, DFW) distribution. When some of group population means are not the same, the F ratio tends to be large.

In a test, if F ratio is large enough, we reject the hypothesis that all group population means are equal.

Problem 2:

- A storeowner wishes to compare the average amount of money high school and college students spend on CDs. He randomly selects **ten** students from **three** different student populations: high school students, undergraduate students, and graduate students. The statistical assumptions required to perform a one-way ANOVA to compare the means of these three groups are reasonable based on the data. A partially completed ANOVA table is provided below:

Problem 2:

Source	Sum of Squares	DF	Mean Square	*F*
Between				
Within	3240			
Total	4450			

One-Way ANOVA

- $SS_T = SS_B + SS_W$
- $d.f._B =$ #of groups -1

  $d.f._w =$ total sample size- #of groups
- $MS_B = SS_B / d.f._B$

  $MS_w = SS_w / d.f._w$
- $F = MS_B/MS_W$

Problem 2:

Source	Sum of Squares	DF	Mean Square	*F*
Between	SS_B	K-1	SS_B / $d.f._B$	MS_B/MS_W
Within	SS_W	N-K	SS_w / $d.f._w$	
Total	$SS_B + SS_W$			

N: total sample size

K: total number of groups

Problem 2:

Source	Sum of Squares	DF	Mean Square	*F*
Between	1210	2	605	5.04
Within	3240	27	120	
Total	4450	29		

(a) df=?

Ans: B

(b) F=?

Ans: C

(c) Reject null?

Ans: No, because $F_{cv}(0.01,2,27)=5.49>5.04$

Table E *F* distribution critical values

		Degrees of freedom in the numerator

Problem 3:

- I am very interested in the use of technology in the classroom. Suppose we do an experiment in which we teach each of **three** sections of an introductory psychology class in a different way. One section of **six** students receives the standard lecture format (blackboard & discussion), a second section of **six** students receives the same lectures with the addition of overhead transparencies, and the third section receives the lectures on the web. The dependent variable is performance on a standardized (final) exam. Do an analysis by hand to test whether there are different effects of different technology use on test performance. If the F is significant, you should conduct post hoc comparisons (Bonferroni approach).

Problem 3:

Subject	GROUP		
	Lecture	**Overheads**	**Web**
1	75	85	92
2	72	74	79
3	64	64	78
4	85	85	96
5	59	65	85
6	78	81	80

One-way ANOVA Steps

1. Compute group means and grand mean
2. Compute sums of squared deviations: SS_W and SS_B (maybe SS_T)

(3. maybe: Check to see if $SS_T = SS_B + SS_W$)

4. Compute MS_B (using df_B)
5. Compute MS_W (using df_W)
6. Compute F and p-value (and create ANOVA source table)
7. Compare p to α (or $F_{observed}$ to $F_{critical}$) and decide…

Problem 3:

Step 1. Compute group means and grand mean.

Subject	GROUP		
	Lecture	Overheads	Web
1	75	85	92
2	72	74	79
3	64	64	78
4	85	85	96
5	59	65	85
6	78	81	80

$M_1=72.2$ $M_2=75.7$ $M_3=85$ GM=77.6

Problem 3:

Step 2. Compute SST , SSW and SSB.

We have: M_1=72.2, M_2=75.7, M_3=85, GM=77.6

Using the formulas,

$$SS_B = \sum_{g=1}^{k} n_g (M_g - GM)^2$$

$$SS_W = \sum_{g=1}^{k} \sum_{i=1}^{n_g} (x_{ig} - M_g)^2$$

compute:

SSB= 528.1111

SSW=1182.167

(Step3: compute SST=1710.278, and Check SST=SSB+SSW)

Problem 3:

Step 4. Compute MS_B

$$MS_B = SS_B / d.f._B$$
$$= 528.1111/2$$
$$= 264.0555$$

Step 5. Compute MS_W

$$MS_w = SS_w / d.f._w$$
$$= 1182.167/15$$
$$= 78.81113$$

Problem 3:

Step 6. Compute F and p-value (and create ANOVA source table)

$$F_{obs} = MS_B / MS_w$$
$$= 264.0555 / 78.81113$$
$$= 3.35$$

Table E: $0.05<\underline{P(F>3.35)=0.0627}<0.1$

Problem 3:

Step 7. Compare p to α (or F_{obs} to F_{cv}) and decide…

$0.05 < \underline{P(F>3.35)=0.0627} < 0.1$

$F_{cv}(0.05,2,15)=3.68 > 3.35$

$F_{cv}(0.10,2,15)=2.70 < 3.35$

Conclusion:

The F is not significant at the level of 0.05.

The F is significant at the level of 0.10.

Bonferroni correction:

If the F is not significant, we don't need to conduct any post hoc comparisons.

But if the F is significant, we should conduct post hoc comparisons. For Bonferroni approach, we need to

(1) conduct 3 independent t tests,

(2) compare these three p-values with $\alpha/3$, or compare three (3*p-values) with α,

(3) decide which 2 groups are significant different.
